**Aim:** Implement a program that demonstrates the concepts of class and objects

**Objective:** To develop the ability of converting real time entity into objects and create their classes.

### Theory:

A class is a user defined blueprint or prototype from which objects are created. It represents the set of properties i.e., members and methods that are common to all objects of one type. In general, class declarations can include these components, in order:

1. Modifiers: A class can be public or has default access.
2. class keyword: class keyword is used to create a class.
3. Class name: The name should begin with a initial letter (capitalized by convention).
4. Superclass (if any): The name of the class's parent (superclass), if any, preceded by the keyword extends. A class can only extend (subclass) one parent.
5. Interfaces (if any): A comma-separated list of interfaces implemented by the class, if any, preceded by the keyword implements. A class can implement more than one interface.
6. Body: The class body surrounded by braces, { }.

An OBJECT is a basic unit of Object-Oriented Programming and represents the real-life entities. A typical Java program creates many objects, which interact by invoking methods.

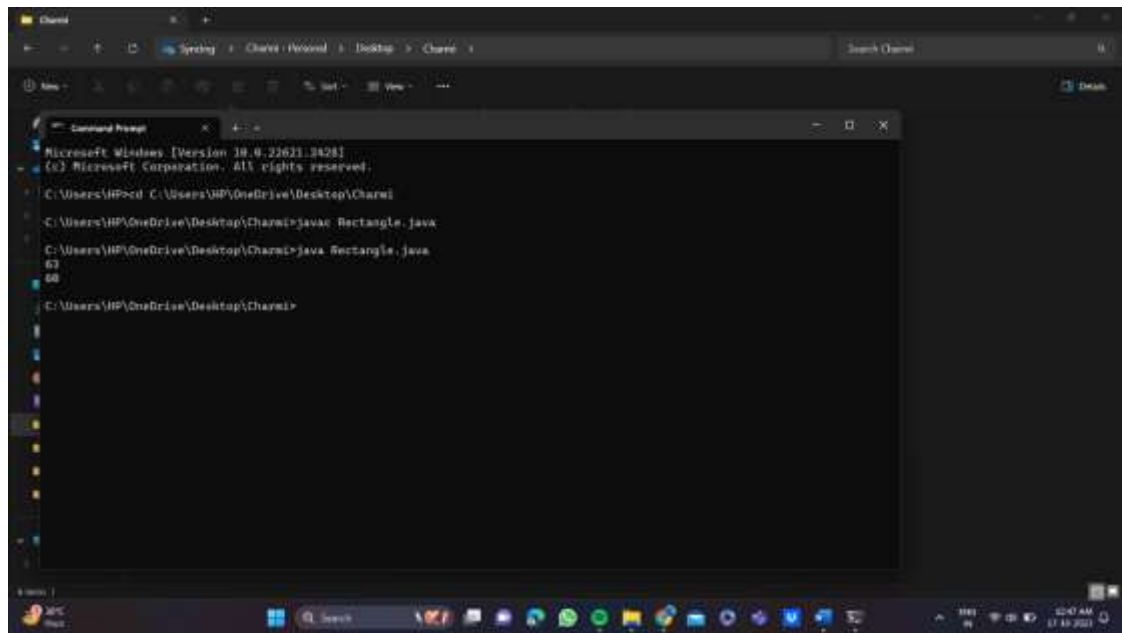

An object consists of:

1. State: It is represented by attributes of an object. It also reflects the properties of an object.
2. Behavior: It is represented by methods of an object. It also reflects the response of an object with other objects.
3. Identity: It gives a unique name to an object and enables one object to interact with other objects.

**Code:**

**1}**

```
class Rectangle{  
    int length;  
    int width;  
    void insert(int l, int w){  
        length=l;  
        width=w;  
    }  
    void calculateArea(){System.out.println(length*width);}  
}  
class TestRectangle1 {  
    public static void main(String args[]){  
        Rectangle r1=new Rectangle();  
        Rectangle r2=new Rectangle();  
        r1.insert(7,9);  
        r2.insert(5,12);  
        r1.calculateArea();  
        r2.calculateArea();  
    }  
}
```

63
68

C:\Users\HP\OneDrive\Desktop\Charvi>
```

## Conclusion:

In Java, you can create a class template by using the `class` keyword followed by the class name. Inside the class, you can declare fields (attributes) to represent the state of objects, define constructors to initialize the object's state, and add methods to define the behavior and actions of the objects.

To create objects from a class, you can use the `new` keyword followed by the class constructor. The created objects can be assigned to variables.

You can access fields and call methods of an object using the dot notation.

In summary, creating a class template and its objects in Java is a straightforward process that involves defining a class with fields and methods, creating objects from the class using the `new` keyword, and accessing fields and methods using the dot notation.
